## **Part B**

Design and implement a digital system that takes the Gray code output from a rotary encoder and displays the rotary shaft position on a 7-segment display

# What a Rotary Encoder is ?

- Definition: Rotary encoders are electromechanical devices used to convert the angular position of a shaft into an electrical signal.
- Commonly used in various applications for measuring rotation and angular displacement.
- Utilizes optical or magnetic sensors to detect changes in position.
- Optical encoders use light and a patterned disc, while magnetic encoders use a magnetized disc and sensors.

# What is a 7 Segment display ?

Seven segment display is an electric component that consists of seven individual LEDs arranged in the form of the number 8 labeled from a to g. The primary function of the seven segment display is to visually represent the decimal numbers from 0 to 9 by illuminating the seven segments.

# Proposed project

- Converting Gray Code output of Rotary encoder to display shafts position to display the shaft's position in a 7 segment display
- Involves 3 basic steps which involves various conversions, which is gray to binary, binary to decimal, decimal to 7 segment display
- Function can be amplified using a microcontroller
- Rigorous testing and further debugging crucial to know its feasibility
- Involves usage of Logic gates for a huge portion

Consider each digit of Gray code as A,B,C,D respectively

A	B	C	D	a	b	c	d	e	f	g
0	0	0	0	1	1	1	1	1	1	0
0	0	0	1	0	1	1	0	0	0	0
0	0	1	1	1	1	0	1	1	0	1
0	0	1	0	1	1	1	1	0	0	1
0	1	1	0	0	1	1	0	0	1	1
0	1	1	1	1	0	1	1	0	1	1
0	1	0	1	1	0	1	1	1	1	1
0	1	0	0	1	1	1	0	0	0	0
1	1	0	0	1	1	1	1	1	1	1
1	1	0	1	1	1	1	1	0	1	1

ABCD	00	01	11	10
00	1	0	1	1
01	1	1	1	0
11	1	1	X	X
10	X	X	X	X

Involves the usage of multiple k-maps

This can be obtained by the standard algorithm for its solution involving isolation of even number of ones to the maximum extent possible

The above example is for first line of gray code which is being converted to binary

# Application of Logic Gates

Logic gates can be utilized to interpret the outcomes from Kmaps to understand whole thing easier

The above is logic gate for kmap given in previous slide

For segment 'a'

The three major lines represent B,C,D

$$a = BC' + B'D' + CD$$

For segment 'c'.

The three major lines represents B,C,D.

$$c = C' + D' + B$$

For segment 'b'

The three major lines represents A,B,D

$$b = C' + D' + B$$

**For segment 'd'**

The three major lines represent A,B,C,D.

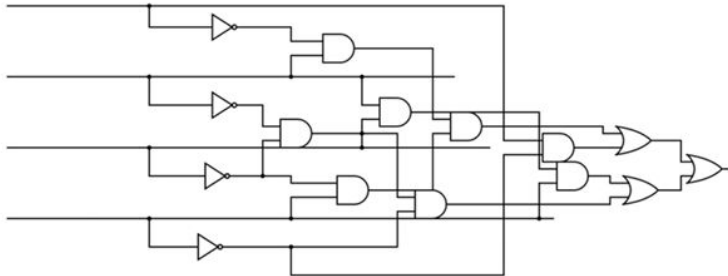

$$d = A + BD + CD + B'D'$$

**For segment 'e':**

The four major lines are A,B,C,D

$$e = A'BC'D + AD' + BCD + B'C'D'$$

**For segment 'f'**

The major lines are A,B,C,D.

$$f = BD + BC + A + B'C'D$$

**For segment 'g'**

The major lines are A,B,C,D

$$g = BD + A + C$$

# Generating the output

The following three  
Are the output
